

# Thermodynamic Results Summary

## Turbofan Engine V1

### Preliminary Thermodynamic Performance Summary

#### 1. Engine Configuration

| Parameter           | Value                          |
|---------------------|--------------------------------|
| Engine Type         | Two-Spool High-Bypass Turbofan |
| Bypass Ratio        | 5.0                            |
| Core Mass Flow      | 20.329 kg/s                    |
| Bypass Mass Flow    | 100.000 kg/s                   |
| Total Air Mass Flow | 120.000 kg/s                   |
| Operating Condition | Static Sea-Level               |

#### 2. Main Thermodynamic Results

| Parameter                              | Value      |
|----------------------------------------|------------|
| Combustor Exit Temperature             | 1400 K     |
| High-Pressure Turbine Exit Temperature | 1003.25 K  |
| Low-Pressure Turbine Exit Temperature  | 637.39 K   |
| Core Nozzle Exit Velocity              | 390.14 m/s |
| Bypass Nozzle Exit Velocity            | 284.74 m/s |

### 3. Engine Performance Summary

| Performance Parameter      | Value           |
|----------------------------|-----------------|
| Core Thrust                | 7.93 kN         |
| Bypass Thrust              | 28.47 kN        |
| Total Net Thrust           | 36.41 kN        |
| Core Thrust Contribution   | 21.79 %         |
| Bypass Thrust Contribution | 78.21 %         |
| Specific Thrust            | 303.38 N/(kg/s) |
| Fuel Mass Flow Rate        | 0.329 kg/s      |
| TSFC                       | 32.53 kg/(kN·h) |

### 4. Key Engineering Observations

- Two-spool high-bypass turbofan thermodynamic cycle successfully completed.
- Core and bypass streams were analysed independently before thrust integration.
- Both exhaust nozzles operated under **unchoked** conditions at the assumed static sea-level operating point.
- Approximately **78%** of the engine thrust was generated by the bypass stream, consistent with modern high-bypass turbofan architectures.
- Total estimated engine thrust was **36.41 kN** under the assumed design conditions.
- GNU Octave was used to implement and verify all thermodynamic calculations.

### 5. Analysis Assumptions

- One-dimensional steady-flow analysis
- Constant specific heats
- Ideal gas behaviour
- Complete combustion
- Fixed component efficiencies
- Static sea-level operation
- Negligible pressure thrust for perfectly expanded nozzles
